

Current velocity measurements in the Strait of Georgia - 1968

Fisheries Research Board of Canada, Biological Station - Tidal plume generation around a promontory: effects on nutrient concentrations and primary productivity

Description: -

-
Buddhist temples -- Japan -- Ise-shi
Shinto shrines -- Japan -- Ise-shi
Isehara-shi (Japan) -- Religion
Design, Industrial -- Italy -- History
Ocean currents -- Georgia, Strait of (B.C. and Wash.)
Current velocity measurements in the Strait of Georgia - 1968
-
no. 162
Chemical technology review ;
no. 178.
Technical report (Fisheries Research Board of Canada) ;
Fisheries Research Board of Canada. Technical report no.
178
Current velocity measurements in the Strait of Georgia - 1968
Notes: Bibliography: p. 7.

Velocity averaging in estuaries characterized by a large tidal range to depth ratio

. Our eventual goal is to assimilate the blended SeaSonde fields into a three-dimensional numerical model to improve short-range current forecasts. From model hindcasts version v201905 , we extract daily velocity and temperature fields spanning November 2014 to January 2020 inclusive.

Tidal plume generation around a promontory: effects on nutrient concentrations and primary productivity

In fact, the measurement of turbulence is a valuable application of the scintillation technique in boundary layer dynamics.

Effects of current velocity on development and survival of lingcod, *Ophiodon elongatus*, embryos

These approaches are perhaps the most realistic in terms of predicting where objects within the ocean will go, but are for various reasons the most difficult to analyze, involving orders of magnitude more information.

A Self

Here, the flushing time for IW originating in Boundary Pass is 128 days, in agreement with other recent SoG flushing time estimates of 125 days. Marker colors in a correspond with the colored y axis in b , e , and h to denote seasonal cycle properties as a function of along-strait distance from Haro Strait. Data from between 50 and 150 m were used to calculate ADCP mean currents and velocity fields apart from the DDL node, where the mean is calculated between 50 and 140 m roughly the seafloor depth.
