20.9: Organometallic Reagents

Almost all processes involving carbon monoxide rely on catalysts, notable examples being described as.

For this reason, understanding these reactions from a kinetics and thermodynamic perspective is critical to ensuring yield, quality and safety of the process. Organometallic compounds are widely used in research and industrial chemical reactions, as well as used as a catalysts to increase the rates of the reaction.

Organometallic Chemistry

PAT technology is used to investigate cross-coupled reactions with regard to kinetics, mechanisms, thermodynamics, and the effect of reaction variables on performance and safety. C-C and C-N coupling reactions in organometallic synthesis, such as Ullmann and Buchwald-Hartwig, reveal how organometallic reactions can be monitored using EasySampler *in situ* sampling. Compounds of Groups IA, IIA, IIB, IIIA, IVA, VA and VIA.
